Preface

Distributed systems have witnessed phenomenal growth in the past few years. The declining cost of hardware, the advancements in communication technology, the explosive growth of the Internet, and our ever-increasing dependence on networks for a wide range of applications ranging from social communication to nancial transactions have contributed to this growth. The breakthroughs in nanotechnology, and wireless communication have opened up new frontiers of applications like sensor networks and wearable computers. We have witnessed the rise and fall of Napster, but we have also seen the rise of peer-to-peer networks from the ashes of Napster. Most applications in distributed computing center around a set of common subproblems. A proper understanding of these subproblems requires a background of the underlying theory and algorithmic issues. This book is a presentation of the foundational topics of distributed systems and their relationships to real-life applications.

The distributed systems community is polarized into two camps. Some practitioners shun the theory as impractical or irrelevant. Some theoreticians pay little attention to the relevance of the theory, and are unable to relate them to real-life results. This book aims at bringing the two communities closer to each other, by striking a better balance between theory and practice.

The book has 21 chapters that can be broadly divided into 5 parts: Part A (Chapters 1–2) deals with background materials that include various interprocess communication techniques, and middleware services. Part B (Chapter 3–6) presents foundational topics, which address system models, correctness criteria, and proof techniques. Part C (Chapters 7–11) presents several important paradigms in distributed systems — topics include logical clocks, distributed snapshots, deadlock detection, termination detection, election, and a few graph algorithms relevant to distributed systems design. Part D (Chapters 12–17) addresses failures and fault-tolerance techniques in various applications — it covers consensus, transactions, group communication, replicated data management, and self-stabilization. Topics like group-communication or consensus are certainly not techniques of fault-tolerance, but their implementations become challenging when process crashes are factored in. Finally, Part E (Chapters 18–21) addresses issues in the real world: these include distributed discrete-event simulation and security, sensor networks, and peer-to-peer networks. Each chapter has a list of exercises that will challenge the readers. A small number of these are programming exercises. Some exercises will encourage the readers to learn about outside materials.

The book is intended for use in a one-semester course at the senior undergraduate or the rst-year graduate level. About 75% of the materials can be covered in one semester. Accordingly, the chapters can be picked and packaged in several different ways. Based on inputs from people who used the material, a theory oriented offering is possible using Chapters 1, 3–17, and 19. For a more practical a vor, use Chapters 1–2, parts of Chapters 3–5, 6, parts of Chapters 7, 9, 11–16, and Chapters 18–21, supplemented by a semester-long project chosen from the areas on replicated data management, wireless networks, group communication, discrete-event simulation, mobile agents, sensor networks, or P2P networks. Readers with background in networking can skip the rst two chapters.

In several chapters, readers will nd topics that do not have an immediate relevance in the practical world. For example, one may wonder, who cares about designing mutual exclusion algorithms now, when application designers have well-developed tools for mutual exclusion? But remember that these tools did not come from nowhere! Some of these are intellectually challenging, but only of historic interest and good sources of enrichment, while others tell readers about what goes on "under

the hood." If the coverage of topics is constrained by immediate practical relevance, then creativity takes a back seat. Those who do not agree to this view can conveniently skip such topics.

Here is a disclaimer: this book is **not** about programming distributed systems. Chapter 2 is only a high-level description that we expect everyone to know, but is **not** an introduction to programming. If programming is the goal, then I encourage readers to look for other materials. There are several good books available.

Several years ago, a well-respected computer scientist advised me about the importance of maintaining a low length-to-content ratio in technical writing. I took his advice to heart while writing this book.

It is a pleasure to acknowledge the help and support of my friends and colleagues from all over the world in completing this project. Steve Bruell helped with improving the initial write-up. Ted Herman has been a constant source of wisdom. Discussions with Sriram Pemmaraju on several topics have been stimulating. Various parts of this book have been used in several offerings of the courses of 22C:166, 22C:194, and 22C:294 at the Computer Science department of the University of Iowa — special thanks to the students of these courses for their constructive criticisms and suggestions. Amlan Bhattacharya, Kajari Ghosh Dastidar, and Shridhar Dighe helped with several examples and exercises. Encouraging feedbacks from readers around the world on the earlier drafts of the material provided the motivation for the project. Thanks to Anand Padmanabhan, Shrisha Rao, Alan Kaminsky, Clifford Neuman, Carl Hauser, Michael Paultisch, Chandan Mazumdar, Arobinda Gupta, and several anonymous reviewers for numerous feedbacks that helped improve the contents of this book. Paul Crockett's early encouragement and Bob Stern's patience have played a key role in completing the manuscript.

Despite best efforts on my part, there will be errors. Conscientious readers are requested to report these to ghosh@cs.uiowa.edu. I thank them in advance.

Dedication

This book is dedicated to the memory of my parents. They would have been the happiest persons to see this in print.

I acknowledge the support of my wife Sumita and my son Soumya for their patience. I sincerely appreciate the encouragement of my former students Chandan Mazumdar and Arobinda Gupta in completing this project.
